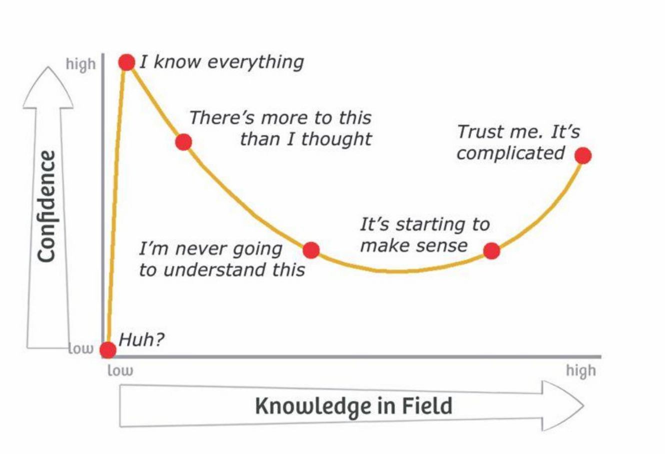
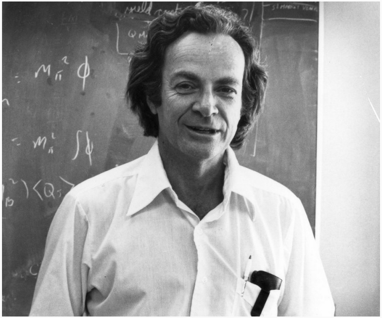
Dunning-Kruger Effect



Kruger, J. and Dunning, D. (1999) *Unskilled and unaware of it: How difficulties in recognizing one's own incompetence lead to inflated self-assessments.* **J Pers Soc Psychol.** 77(6) pp. 1121–1134.

"Knowledge isn't free. You have to pay attention."

Richard P. Feynman



Roadmap

An overview

CNNs *(Convolutional Neural Networks)* are used for image classification and other computer vision tasks because they are able to automatically learn features from raw data. This is useful for tasks where manual feature engineering is difficult or impractical.

VAEs *(Variational Autoencoders)* are used for tasks such as image generation and anomaly detection because they are able to learn a compact representation of a dataset and generate new samples from this representation.

GANs *(Generative Adversarial Networks)* are used for tasks such as image generation and data augmentation because they are able to generate new data samples that are similar to a given dataset.

NLP *(Natural Language Processing)* is important for tasks such as language translation, text classification, and language generation because it allows computers to process and understand human language.

CNN, VAE, GAN & NLP

CNN

Motivating Factors

- A **Convolutional Neural Network (CNN)** is a type of neural network that is particularly well-suited for image classification and object recognition tasks. It is designed to process data with a grid-like topology, such as an image,.
- **CNNs** are composed of several types of layers, including convolutional layers, pooling layers, and fully connected layers.

❶ The convolutional layers apply filters to the input data, which are used to detect patterns and features in the data.

❷ The pooling layers reduce the spatial dimensions of the data, which helps to reduce the complexity of the model and make it more robust to small translations of the input data.

❸ The fully connected layers combine the features learned by the convolutional and pooling layers to make a prediction.

CNN

Use Cases

Image classification
Object detection
Image segmentation
Medical image analysis
Medical image analysis
Self-driving cars

VAE

Motivating Factors

- A **Variational Autoencoder (VAE)** is a type of deep learning model that is used to learn latent representations of data. It is a generative model, which means that it can generate new samples of data that are similar to the training data.
- **VAEs** are trained to encode the data into a low-dimensional latent space and then decode the latent representation back into the original data space. During training, the **VAE** learns to reconstruct the input data, while also trying to enforce a constraint on the latent space that encourages it to represent the data in a meaningful way.
- The constraint that is used in a **VAE** is called the variational lower bound. This lower bound is maximized during training, which encourages the latent space to be structured in a way that is useful for generating samples that are similar to the training data.

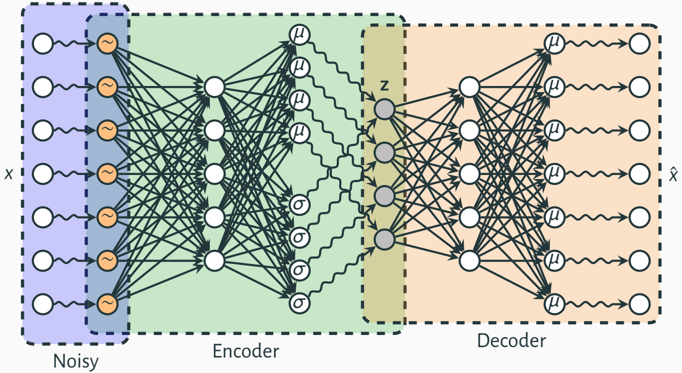
VAE

Use Cases

- Generative modeling
- Anomaly detection
- Data compression
- Representation learning
- Semi-supervised learning

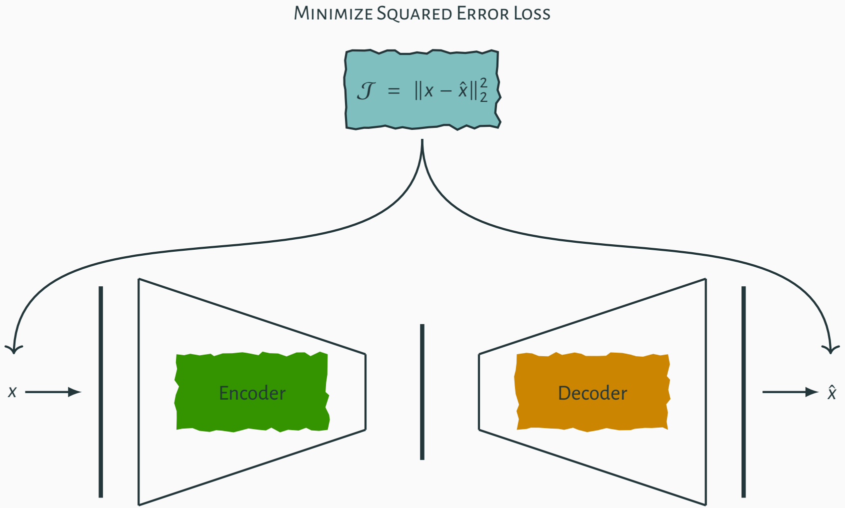
VAE

Architecture of Variational Autoencoder



VAE

Loss of Vanilla Autoencoder



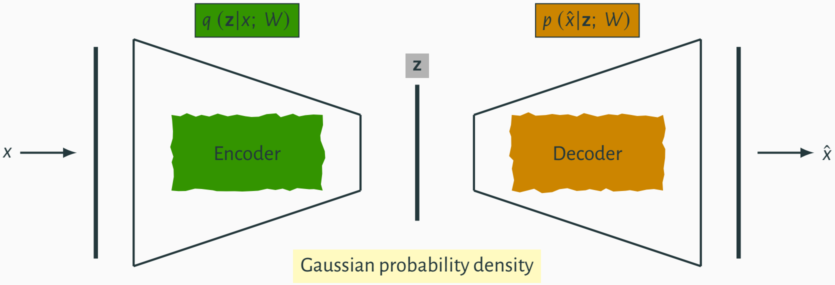
VAE

Loss of Variational Autoencoder

$$\mathcal{J} = -\,\mathfrak{E}_{\mathbf{z}\sim q\left(\mathbf{z}|x^{(i)};\,W\right)}\left[\log p\left(\hat{x}^{(i)}|\mathbf{z};\,W\right)\right] + \mathcal{KL}\left(q\left(\mathbf{z}|x^{(i)};\,W\right)\,\|\,p(\mathbf{z})\right)$$

Expected negative log likelihood term wrt to encoder distribution

Kullback-Leiber divergence term where $p(\mathbf{z}) \sim \mathcal{N}\left(\mu = 0,\, \sigma^2 = 1\right)$



VAE

$\mathcal{KL}$ Loss Derivation

In a **VAE**, the latent vector **z** is calculated by:

$$\mathbf{z} = \mu + \sigma \bigodot \epsilon \qquad \text{where} \quad \epsilon \sim \mathcal{N}\left(0_z, \mathbb{1}_{z\times z}\right)$$

μ and σ denote respectively the mean and variances for the latent vector **z**. The encoder learns to output the two vectors $\mu \in \mathbb{R}^z$, and $\sigma \in \mathbb{R}^z$. The encoder distribution is

$$q\left(\mathbf{z}|x^{(i)}\right) = \mathcal{N}\left(\mathbf{z}|\mu\left(x^{(i)}\right), \Sigma\left(x^{(i)}\right)\right) \qquad \text{where} \quad \Sigma = \begin{bmatrix} \sigma_l^2 & 0 & 0 & \cdots \\ 0 & \sigma_2^2 & 0 & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_l^2 \end{bmatrix}$$

The latent prior is given by

$$p(\mathbf{z}) = \mathcal{N}\left(0_z, \mathbb{1}_{z\times z}\right)$$

$$\boxed{\mathcal{KL}\left(q\left(\mathbf{z}|x^{(i)}; W\right) \| p(\mathbf{z})\right) = \frac{1}{2}\left[-\sum_i \left(\log \sigma_i^2 + 1\right) + \sum_i \sigma_i^2 + \sum_i \mu_i^2\right]}$$

GAN

An Overview

- A **Generative Adversarial Network (GAN)** is a type of deep learning model designed to generate new, synthetic samples of data. It consists of two networks: a generator network and a discriminator network. The generator network generates synthetic samples, while the discriminator network tries to distinguish between the synthetic samples and real samples of data.
- During training, the generator and discriminator networks are trained concurrently, with the generator trying to generate synthetic samples that are indistinguishable from real samples, and the discriminator trying to correctly classify the samples as either real or synthetic. The generator is trained to improve its synthetic samples based on the feedback from the discriminator, and the discriminator is trained to become more sensitive to synthetic samples.
- The goal of a **GAN** is to learn a generative model that can produce synthetic samples that are similar to the training data. **GANs** have been used for a variety of tasks, including image generation, audio synthesis, and natural language processing.

GAN

Use Cases

- Image generation
- Image style transfer
- Text-to-image synthesis
- Video prediction
- Text-to-speech synthesis
- Super-resolution
- Data augmentation
- Domain adaptation

NLP

Purpose of NLP

- **Natural Language Processing (NLP)** is a field of artificial intelligence and computer science that focuses on the interaction between computers and humans using natural language.
- **NLP** involves the development of algorithms and models that can understand, interpret, and generate human language.
- **NLP** is used in a wide range of applications, including machine translation, question answering, text summarization, text classification, and sentiment analysis.

NLP

Use Cases

Part-of-speech tagging

Named entity recognition

Sentiment analysis

Machine translation

Text summarization

NLP

General Process in Julia

1. Preprocess the text data by lowercasing, removing punctuation, and splitting the text into individual tokens *(e.g., words or subwords)*.
2. Build a vocabulary of the most common tokens in the text data.
3. Encode the text data as a sequence of integers using the vocabulary.
4. Pad the encoded sequences to the same length to make them suitable for input to a model.
5. Define the **NLP** model using a library such as `Flux.jl` or `Knet.jl`.
6. Train the model using gradient descent and a suitable loss function.
7. Use the trained model to make predictions on new data.

Transfer Learning

Transfer Learning

Driving Forces

- **Transfer Learning** is a machine learning technique in which a model that has been trained on one task is re-purposed on a second related task. **Transfer Learning** can be used to improve the performance of the second task by leveraging the knowledge learned from the first task.
- One common use of **Transfer Learning** is to fine-tune a pre-trained model on a new dataset. For example, a pre-trained image classification model that has been trained on a large dataset such as `ImageNet` can be fine-tuned on a smaller dataset of a different but related task, such as detecting objects in medical images. Fine-tuning the pre-trained model on the new dataset can lead to improved performance compared to training a model from scratch on the smaller dataset.
- **Transfer Learning** is useful because it allows a machine learning model to learn from a large amount of data, even if the data is not directly related to the task at hand. It can also be used to speed up the training process, since the model does not need to be trained from scratch.

Transfer Learning

Use Cases

Image classification

Natural language processing

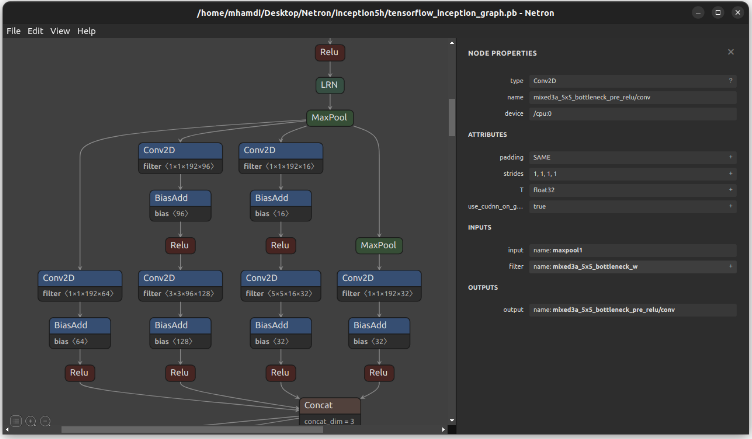
Speech recognition

Computer vision

Robotics

Transfer Learning

Netron



https://github.com/lutzroeder/netron

Transfer Learning

General Process in Julia

1. Load the pre-trained model *(e.g., a convolutional neural network trained on* `ImageNet`*)*.
2. Replace the final layer (or layers) of the pre-trained model with a new, untrained layer (or layers) that is suitable for your target task.
3. Freeze the weights of the pre-trained layers to prevent them from being updated during training.
4. Load your dataset and split it into training and validation sets.
5. Use the training set to fine-tune the weights of the new layer (or layers) using gradient descent and a suitable loss function.
6. Monitor the performance of the model on the validation set and adjust the hyperparameters *(e.g., learning rate)* as needed.
7. When you're satisfied with the performance of the model on the validation set, you can use it to make predictions on the test set or on new data.

Reinforcement Learning

Reinforcement Learning

Synopsis

- **Reinforcement Learning** is a type of machine learning in which an agent learns to interact with its environment in order to maximize a reward. It involves learning to map situations (called states) to actions that will maximize a reward. The agent receives feedback in the form of rewards and penalties for its actions, which it uses to adjust its behavior accordingly.
- In **reinforcement Learning**, the goal is to learn a policy that maximizes the cumulative reward over time. The agent learns this policy through trial and error, by exploring different actions in different states and receiving feedback in the form of rewards or penalties.
- **Reinforcement Learning** is used in a variety of applications, including control systems, game playing, and natural language processing. It has been successful in a number of tasks, including teaching a computer to play chess and Go at a high level.
